

LEG DISSECTION

SPRING 2021

My first cadaver dissection project was on a left cadaver leg, which was severed at the upper thigh. Since this was my first cadaver dissection I focused on getting used to dissection techniques, such as reverse scissoring, cutting superficially with a scalpel, using a probe, etc. I began to focus on the thigh anatomy, first isolating and identifying each muscle. I then worked my way into the knee joint and foot. I spent the most time on the foot because I found it the most interesting. I first isolated the muscles and tendons of the foot and then I cut through some of the superficial muscles to reveal the deeper muscles and the bones. I eventually made my way back up to the knee to study the mechanics of moving the knee and ankle joints.

These photos are not mine; I do not have any photos of my projects, but these photos are very similar to the work I've done
